

# A Linear Spac Algorithm for **Computing Maximal** Common Subsequences

D.S. Hirschberg Princeton University

The problem of finding a longest common subsequence of two strings has been solved in quadratic time and space. An algorithm is presented which will solve this problem in quadratic time and in linear space.

Key Words and Phrases: subsequence, longest common subsequence, string correction, editing CR Categories: 3.63, 3.73, 3.79, 4.22, 5.25

# $\frac{1}{\sqrt{2}}$

The problem of finding a longest common subsequence of two strings has been solved in quadratic time and space  $[1, 3]$ . For strings of length 1,000 (assuming coefficients of 1 microsecond and 1 byte) the solution would require  $10^6$  microseconds (one second) and  $10^6$ bytes (1000K bytes). The former is easily accommodated, the latter is not so easily obtainable. If the strings were of length 10,000, the problem might not be. solvable in main memory for lack of space.

We present an algorithm which will solve this probas a problem an argorithm which will solve this problem  $\frac{1}{2}$  strings of  $\frac{1}{2}$  seconds of  $\frac{1}{2}$  seconds  $\frac{1}{2}$  seconds assuming coefficients of 2 microseconds and 10 bytes, for strings of length 1,000 we would require 2 seconds and  $10K$  bytes; for strings of length  $10,000$  we would require a little over 3 minutes and 100K bytes. The a finite over 5 minutes and foots bytes.

### Proof of Correctness of Algorithm A

To find  $L(i, j)$ , let a common subsequence of that  $\frac{1}{2}$  can do not define that by the common babbed choice of that for  $c_1$  as a complete of  $c_1$ ,  $c_2$  is  $c_3$ ,  $c_4$ ,  $c_5$ ,  $c_6$ ,  $c_7$ ,  $c_8$ ,  $c_9$ ,  $c_1$ we can do no better than by taking  $c_p = a_i$  and looking<br>for  $c_1 \cdots c_{p-1}$  as a common subsequence of length  $\mathbf{r}$ (i, i<sub>)</sub>  $\mathbf{r}$  i<sub>j</sub>c, i<sub>)</sub>  $\mathbf{r}$  iii)  $\mathbf{r}$  $I(f)$  is a being  $n_1, -1$  and  $D_1, -1$ , then, in this  $\sum_{i=1}^{n} \sum_{j=1}^{n} \sum_{j=1}^{n}$ 

 $\mathbf{F}$  **P(i)**  $\mathbf{F}$  is a solution to  $\mathbf{F}$  is a solution to  $\mathbf{F}$  . If  $\mathbf{F}$  is a solution to  $\mathbf{F}$  is a solution to  $\mathbf{F}$ If  $c_p$  is  $a_i$ , then a solution C to problem  $(A_{1i}, B_{1j})$  [written  $P(i, j)$  will be a solution to  $P(i, j - 1)$  since  $b_j$  is not used. Similarly, if  $c_p$  is  $b_j$ , then we can get a soluthen about  $\sum_{i=1}^n a_i = a_i$ ,  $\sum_{i=1}^n a_i = a_i$ ,  $\sum_{i=1}^n a_i = a_i$ ,  $\sum_{i=1}^n a_i = a_i$ such to  $\frac{1}{3}$  (i) determining the length of the solution, it is in the solution of t then a solution to either  $P(i - 1, j)$  or  $P(i, j - 1)$  will suffice. In determining the length of the solution, it is seen that  $L(i, j)$  [corresponding to  $P(i, j)$ ] will be the

# Time and Space Analysis of Algorithm A

The if statement in Algorithm A will be executed exactly mn times. Input and output arrays require  $m + n + (m + 1)(n + 1)$  locations. Thus Algorithm A requires  $O(mn)$  time and  $O(mn)$  space.

# **Algorithm B**

In Algorithm A, the derivation of row *i* of matrix L  $(L(i, 1), L(i, 2), \ldots, L(i, n))$  requires only row  $i-1$ of matrix  $L$ . Thus, a slight modification yields Algorithm B, which accepts as input strings  $A_{1m}$  and  $B_{1n}$  and produces as output vector  $LL$  where  $LL(j)$  will have the value  $L(m, j)$ .

**1. ALG B** (*m, n, A, B, LL*)

## Proof of Correctness of Algorithm B

Algorithm B is Algorithm A with  $K(0, j)$  in statement 4 of ALG B having the same value as  $L(i - 1, j)$ in statement 3 of ALG A and  $K(1, j)$  receiving the same value as  $L(i, j)$ . We show this by induction on i.

For  $i = 1$ ,  $L(i - 1, j)$  is zero (initialized in statement 1 of ALG A). In ALG B,  $K(0, j)$  received in statement 3 the value of  $K(1, j)$ , which was just initialized to zero in statement 1.

Assume  $K(0, j)$  has the same value as does  $L(i-1, j)$ . Then  $K(1, j)$  receives the same value as  $L(i, j)$  since the assignment statements within the inner loops of ALG A and ALG B are equivalent. For the next iteration,  $K(0, j)$  receives (in statement 3 of ALG B) the value of  $K(1, j)$  which has the value of  $L(i, j)$  as shown above.  $\square$ 

# Time and Space Analysis of Algorithm B

As in Algorithm A, the **if** statement in Algorithm B is executed exactly  $mn$  times. Input and output arrays require  $m + n + (n + 1)$  locations. Local storage *requires*  $2(n + 1)$  locations. Thus Algorithm B requires  $O(mn)$  time and  $O(m + n)$  space.

We shall show that using Algorithm B for appropriate substrings of  $A$  and  $B$  will enable us to recover a maximal common subsequence of  $A$  and  $B$  in linear define  $\mathbf{c}$  is the maximum length of common length of common length of common length of common length of common

Define  $L^*(i,j)$  to be the maximum length of common subsequences of  $A_{i+1,m}$  and  $B_{j+1,n}$ .

We note that  $L(i, j)$   $j = 0 \cdots n$  are the maximum lengths of common subsequences of  $A_{1i}$  and various prefixes of  $B_{1n}$ . We also note that  $L^*(i, j)$   $j = 0 \cdots n$ are the maximum lengths of common subsequences of **342** Communications June 1975

and using the theorem below, we shall be able to determine a prefix  $B_1$  of B which can be matched with the first half  $A_1$  of A (and the corresponding suffix  $B_2$  of B matched with the last half  $A_2$  of  $A$ ) such that a maximal common subsequence (mcs) of  $A_1$  and  $B_1$  concatenated with an mcs of  $A_2$  and  $B_2$  will be an mcs of A and B.

may  $D$ cime  $\ln(r)$  =  $\lim_{n \to \infty} \ln(r, y) + \ln(r, y)$ . THEOREM. For  $0 \le i \le m$ ,  $M(i) = L(m, n)$ .

**PROOF.** Let  $M(i) = L(i, j) + L^*(i, j)$  for some j. Let  $S(i, j)$  be any maximal common subsequence of  $A_{1i}$  and  $B_{1i}$ ; let  $S^*(i, j)$  be any maximal common subsequence of  $A_{i+1,m}$  and  $B_{j+1,n}$ . Then  $C = S(i, j) \mid S^*(i, j)$ is a common subsequence of  $A_{1m}$  and  $B_{1n}$  of length  $M(i)$ . Thus  $L(m, n) \geq M(i)$ .

Let  $S(m,n)$  be any maximal common subsequence of  $A_{1m}$  and  $B_{1n}$ .  $S(m,n)$  is a subsequence of B that is  $S_1$  (a subsequence of  $A_{1i}$ )  $\mid S_2$  (a subsequence of  $A_{i+1,m}$ ). Then there exists j such that  $S_1$  is a subsequence of  $B_{1j}$  and  $S_2$  is a subsequence of  $B_{j+1,n}$ . By definition of *L* and  $L^*$ ,  $|S_1| \le L(i, j)$  and  $|S_2| \le L^*(i, j)$ . Thus  $L(m,n) = |S(m,n)| = |S_1| + |S_2| \le L(i,j) + L^*(i,j)$  $\leq M(i)$ .  $\Box$ 

# Algorithm C

We now apply the above theorem recursively to divide a given problem into two smaller problems until we obtain a trivial subproblem.

Algorithm C accepts as input strings  $A$  and  $B$  (of lengths  $m$  and  $n$ ) and produces as output a common subsequence C of A and B that is of maximum length  $p$ .

ALG C  $(m, n, A, B, C)$

```
C \leftarrow C1 \mid C2;
```

```
end
```
6.

## Proof of Correctness of Algorithm C

 $L(1i)$  produced by the first call to ALG B in line 3 is equal to  $L(i, j)$ . This was shown in the proof of correctness of Algorithm B. Similarly,  $L2(j)$  is equal to the maximum length of common subsequences (max lcs) of  $\hat{A}_{m,i+1}$  and  $\hat{B}_{n,n-j+1}$  by the proof of correctness of Algorithm B.

6

Thus

$$
L2(n - j) = \max \operatorname{lcs} \operatorname{of} A_{m,i+1} \operatorname{and} \hat{B}_{n,j+1},
$$
  
= max  $\operatorname{lcs} \operatorname{of} A_{i+1,m}$  and  $B_{j+1,n}$ ,  
=  $L^*(i, j)$ .

By our theorem, we can find  $k$  (as in line 4) such that  $L(i, k) + L^*(i, k) = L(m, n)$ . So there must exist solutions C1 and C2 to the subproblems  $(A_{1i}, B_{1k})$  and  $(A_{i+1,m}, B_{k+1,n})$  such that  $Cl \mid C2$  will be a common subsequence of A and B of length  $L(m, n)$ . The solutions to the subproblems are obtained in line 5 and are added together in line 6 to obtain the final output.  $\Box$ 

#### Time Analysis of Algorithm C

For  $P(1, n)$  we look for a single match. For some constants  $c_1$  and  $c_2$  this is time-bounded by  $c_1 \cdot n + c_2$ .

For  $P(2m, n)$ , let operations on vectors that are linear in *m* or *n* be time-bounded by  $c_3 \cdot m + c_4 \cdot n + c_5$ . That leaves two calls to ALG B and two calls to ALG C. The calls to ALG B are bounded by  $c_6$  *mn* by time analysis of ALG B. Assume  $P(m, n)$  is time-bounded by  $d_1 \cdot mn + d_2 (d_1 \geq c_1, d_2 \geq c_2)$ . Then the calls to ALG C will be time-bounded by  $d_1 \cdot mk + d_2$  and  $d_1 \cdot m(n - k)$  $f + d_2$ . Thus a total time-bound T for  $P(2m,n)$  will be

$$
T = (d_1 + c_6) \cdot mn + c_3 \cdot m + c_4 \cdot n + c_5 + 2d_2.
$$

For  $n \geq 1$ ,  $T \leq (d_1 + c_6 + c_3 + c_4 + c_5 + d_2) \cdot mn + d_2$ . For  $n = 0$ , let  $T \le d_2$ . Then to be consistent with our assumption on the time-bound of  $P(m, n)$ , we must have  $d_1 + c_6 + c_3 + c_4 + c_5 + d_2 \leq 2d_1$ , which is realizable by letting  $d_1 = c_6 + c_3 + c_4 + c_5 + d_2$ .

Thus Algorithm C has an  $O(mn)$  time bound.

### Space Analysis of Algorithm C

We assume that vectors  $A$  and  $B$  are in common by giving initial restors it and Theorem contribution, the calls to ALG B use the calls of the by giving initial and final locations.<br>Then, during execution, the calls to ALG B use

temporary storage which is linear in  $m$  and  $n$  (see space analysis of Algorithm  $B$ ). It is seen that, exclusive of recursive calls to ALG C, ALG C uses a constant amount of memory space. There are  $2m - 1$  calls to ALG C (proven below), and so ALG C requires memory space proportional to m and n, i.e.  $O(m + n)$ **Proof That There Are** 2m -- 1 **Calls to ALG** C

### Proof That There Are  $2m - 1$  Calls to ALG C

 $2.1$   $\frac{1}{2}$   $\frac{1$  $\text{Let } m \geq 2$  ,  $\text{If } n \geq 2$  and  $\text{Let } n$  is extended the area 2m -- 1 and 1 and 1 and 2m -- 1 and 2  $2 \cdot 1 - 1 = 1$  call to ALG C.<br>Assume that for  $m \le 2^r = M$  there are  $2m - 1$ 

calls to ALG C. For  $m' \leq 2^{r+1} = 2M$ , i will be set equal to at most  $M$  in line 2. There will be two calls to ALG C with first parameters  $m_1$  and  $m_2$  such that  $B_{\text{max}}$  and  $C$  with the parameters  $m_1$  and  $m_2$  such that  $m_1 + m_2 = m$  and both  $m_1$  and  $m_2$  are at his initial calls the initial calls in the initial By assumption, each of these calls will generate a total of  $2m_i - 1$  calls to ALG C. Adding in the initial call results in a total of:  $(2m_1 - 1) + (2m_2 - 1) + 1 =$  $2(m_1 + m_2) - 1 = 2m' - 1$  calls.  $\Box$ 

Algorithm C can be modified to find the edit distance between two strings (as defined in [3]). In this case we would seek to minimize  $D(m, n)$ , the cost of a trace from  $A_{1m}$  to  $B_{1n}$ . The corresponding statement of our theorem would be: for all *i*,

$$
D(m, n) = \min_{0 \leq i \leq n} \{D(i, j) + D^*(i, j)\}.
$$

The modified Algorithm C would split problems in half by the above theorem, using a modified Algorithm B to evaluate  $D(i, j)$  and  $D^*(i, j)$ , and call itself recursively.
